

Transcript - Testing with a Postman Mock Server

0:05

Testing multiple workflow actions together is useful when a workflow uses dynamic variables in multiple actions.

0:12

By adding actions using dummy API endpoints directly below the workflow action that you would like to test, you can send the actions responses to a test server for review.

0:24

As we previously walked through testing individual actions using webhook dot site, let's look at how we can use Postman mock server to test several workflow actions at once.

0:35

Please note Onetrust is not responsible for outcomes using external tools as these are not proprietary to Onetrust.

0:43

If you have not created a Postman mock server and would like to test along, please pause the video here and follow the instructions by Postman on how to do so, then return.

0:53

Once you have successfully set up your mock server in Postman's web app or dedicated application, locate the configured mock server and select Copy Mock URL.

1:04

Then navigate back to your integration workflow in one trust.

1:08

Find the workflow actions that you would like to receive the responses for, then add a new POST action directly below each one.

1:16

Configure the request so that you are using Postman's mock URL as the request URL, and ensure that the method is set to POST To view the response from a preceding action, the request body must be empty.

1:30

If there is any content in the body field, the integration workflow will send this data as part of the request instead.

1:38

For demo purposes, we will have two test workflow actions.

1:43

For the first action, we are looking to push the response of a request to the Postmin mock server.

1:48

Hence, the body of the test action will remain empty.

1:52

The second action will be used to test free marker and dynamic values.

1:57

Hence, here we will provide a free marker script in the request body.

2:01

Once you have configured all of your POST calls, close any open actions and save your integration workflow.

2:08

Click the context menu icon in the top right corner and adjust the event data if necessary.

2:14

Then select Test to trigger the integration.

2:18

If the integration workflow processes as intended, you should see both requests appear in Postman.
